

Python Programming

Lecture 3 Iteration

3.1 Iteration: while

The while statement

```
1 n = 5
2 while n > 0:
3     print(n)
4     n = n - 1
5
6 print('Blastoff!')
```

```
5
4
3
2
1
Blastoff!
```

1. Evaluate the condition, yielding True or False.
2. If the condition is false, exit the while statement and continue execution at the next statement.
3. If the condition is true, execute the body and then go back to step 1.
 - This type of flow is called a **loop** because the third step loops back around to the top.
 - We call each time we execute the body of the loop an **iteration**.

- The body of the loop should change the value of one or more variables so that eventually the condition becomes false and the loop terminates.
- If the loop repeats forever, it results in an **infinite loop**.

```
1 n = 10
2 while True:
3     print(n)
4     n = n - 1
5 print('Done!')
```

- What will happen if you run this?
- Ctrl+C to terminate it.

- Finishing iterations with **break**

```
1 while True:
2     line = input('Please enter:')
3     if line == 'done':
4         break
5     print(line)
6 print('Done!')
```

- Finishing iterations with **continue**

```
1 while True:
2     line = input('Please enter:')
3     if line == '#':
4         continue
5     if line == 'done':
6         break
7     print(line)
8 print('Done!')
```

Example 1: Even and Odd

```
1 numbers = [12, 37, 5, 42, 8, 3]
2 even = []
3 odd = []
4 while len(numbers) > 0:
5     x = numbers.pop()
6     if x % 2 == 0:
7         even.append(x)
8     else:
9         odd.append(x)
10 print(even)
11 print(odd)
```

```
[8, 42, 12]
[3, 5, 37]
```

Example 2: BMI Calculator v2.0

```
1 print("BMI指数计算器\n")
2 while True:
3     try:
4         inp_1 = input('请输入您的体重(kg):\n')
5         weight = float(inp_1)
6         break
7     except:
8         print('请输入数字')
9 while True:
10    try:
11        inp_2 = input('请输入您的身高(cm):\n')
12        height = float(inp_2)
13        break
14    except:
15        print('请输入数字')
```

Example 3: Greatest common divisor

```
1 a=int(input('Enter the 1st number:'))
2 b=int(input('Enter the 2nd number:'))
3 if a >= b:
4     x = a
5     y = b
6 else:
7     x = b
8     y = a
9 while y!=0:
10     r = y
11     y = x%y
12     x = r
13 print(x)
```

- Least common multiple?

Example 4: Hot Potato Game

- To begin, let's consider the children's game Hot potato. In this game children line up in circle and pass an item from neighbor to neighbor as fast as they can. At a certain point in the game, the action is stopped and the child who has the item (the potato) is removed from the circle. Play continues until only one child is left.
- This game is a modern-day equivalent of the famous Josephus problem.

```
1 name_list = ['a', 'b', 'c', 'd', 'e', 'f']
2 i = 1
3 while len(name_list) > 1:
4     if i % 7 == 0:
5         y = name_list.pop()
6     else:
7         y = name_list.pop()
8         name_list.insert(0, y)
9         # print(name_list)
10    i = i + 1
11 print(name_list)
```

Example 5: Finding prime numbers

```
1 i = 2
2 while i < 100:
3     j = 2
4     while j**2 <= i:
5         if i%j == 0 :
6             break
7         j = j + 1
8     if j**2 > i:
9         print(i)
10    i = i + 1
```

3.2 Iteration: for

Definite loops using for

- **for** statement works on the lists.

```
1 friends = ['Joseph', 'Glenn', 'Sally']
2 for friend in friends:
3     print('Happy New Year:', friend)
4 print('Done!')
```

```
Happy New Year: Joseph
Happy New Year: Glenn
Happy New Year: Sally
Done!
```

- We refer to the while loop as an indefinite loop because it continues executing until a specific condition becomes False, whereas the for loop iterates over a known set of items, running as many times as there are items in the set.
- In particular, friend is the iteration variable for the for loop. The variable friend changes for each iteration of the loop and controls when the for loop completes. The iteration variable steps successively through the three strings stored in the friends variable.

- The indentation errors are common.
- Python uses indentation to determine when one line of code is connected to the line above it. Some languages require the "end" statement.
- Always indent the line after the for statement in a loop.

```
1 friends = ['Joseph', 'Glenn', 'Sally']  
2 for x in friends:  
3     print('Happy New Year:', x)  
4     print('Done!')
```

IndentationError: expected an indented block

```
1 message = "Hello Python world!"  
2     print(message)
```

IndentationError: unexpected indent

- Forgetting to indent additional lines (logical error)

```
1 friends = ['Joseph', 'Glenn', 'Sally']
2 for x in friends:
3     print('Happy New Year:', x)
4 print('Looking forward to seeing you,', x)
```

```
Happy New Year: Joseph
Happy New Year: Glenn
Happy New Year: Sally
Looking forward to seeing you, Sally
```

```
1 friends = ['Joseph', 'Glenn', 'Sally']
2 for x in friends:
3     print('Happy New Year:', x)
4     print('Looking forward to seeing you,', x)
```

```
Happy New Year: Joseph
Looking forward to seeing you, Joseph
Happy New Year: Glenn
Looking forward to seeing you, Glenn
Happy New Year: Sally
Looking forward to seeing you, Sally
```

range function

- The **range** function generates a sequence of integers.
- It often used to control the number of iterations in a for loop.

```
1 for value in range(1,4):  
2     print(value)
```

```
1  
2  
3
```

```
1 >>> list(range(1,6))  
2 [1, 2, 3, 4, 5]  
3 >>> list(range(6))  
4 [0, 1, 2, 3, 4, 5]  
5 >>> list(range(1, 10, 2))  
6 [1, 3, 5, 7, 9]  
7 >>> list(range(10, 1, -2))  
8 [10, 8, 6, 4, 2]
```

- Example: generate a list of square numbers

```
1 squares = []  
2 for value in range(1,11):  
3     square = value**2  
4     squares.append(square)  
5 print(squares)
```

```
[1, 4, 9, 16, 25, 36, 49, 64, 81, 100]
```

Replicate the functionality of list functions using for loops.

sum(): how to calculate $1 + 2 + 3 + \dots + 100$?

```
1 total = 0
2 for value in range(1, 101):
3     total = value + total # total+=value
4 print(total)
```

len()

```
1 a_list = [3, 41, 12, 9, 74, 15]
2 count = 0
3 for x in a_list:
4     count = count + 1
5 print('Count: ', count)
```

max(), min()

```
1 a_list = [3, 41, 12, 9, 74, 15]
2 largest = a_list[0]
3 for x in a_list:
4     if x > largest :
5         largest = x
6 print('Largest:', largest)
```

sorted(): sorting is a much more complicated and interesting topic.

Nested Loops

```
1 x = []  
2 for i in range(1,4):  
3     x.append([])  
4     for j in range(1,4):  
5         x[i-1].append(1)  
6 print(x)
```

```
[[1, 1, 1], [1, 1, 1], [1, 1, 1]]
```

```

1 x = []
2 for i in range(1,4):
3     x.append([])
4     for j in range(1,i+1):
5         x[i-1].append(1)
6 print(x)

```

```
[[1], [1, 1], [1, 1, 1]]
```

```

1 for i in range(1,4):
2     for j in range(1,i+1):
3         print(i, end=" ")
4     print()

```

```

1
2 2
3 3 3

```

- The default value of end is `\n` meaning that after the print statement it will print a new line. So simply stated end is what you want to be printed after the print statement has been executed

```

1 for i in range(1,4):
2     for j in range(i):
3         print(i,end="+")
4     print()

```

```

1+
2+2+
3+3+3+

```

Summary

- Iteration
